#### Abstract

In Paper I (Mickaelian et al. 1999), we compared the surface density of QSOs in the Bright Quasar Survey (BQS) and in the First Byurakan Survey (FBS) and concluded that the completeness of the BQS is of the order of $70 \%$ rather than $30-50 \%$ as suggested by several authors. A number of new observations recently became available, allowing a re-evaluation of this completeness. We now obtain a surface density of QSOs brighter than $B=16.16$ in a subarea of the FBS covering $\sim 2250 \mathrm{deg}^{2}$, equal to $0.012 \mathrm{deg}^{-2}$ (26 QSOs), implying a completeness of $53 \pm 10 \%$.

Subject headings: Quasars - Surveys

## 1. INTRODUCTION

In Paper I, by comparing the FBS (Markarian et al. 1989) and BQS (Green et al. 1986) surveys in their area in common, we derived a completeness of $\sim 70 \%$ for the BQS. A number of bright AGNs have since been discovered in the area which, together with our new spectroscopic observations, allowed us to refine our previous estimate of the BQS completeness.

## 2. OBSERVATIONS

We have obtained new spectra for 11 FBS objects. The observations were carried out on November 25, 1998 and January 14-15, 1999 at the Byurakan Astrophysical Observatory (BAO) and at the Observatoire de Haute-Provence (OHP), respectively. The journal of observations is given in Table 1, together with relevant data.

Seven of the newly observed objects are stars, including FBS $2308+425$ (at $b=-16.3^{\circ}$ ) which is associated with a ROSAT RASS (Voges et al. 1999) X-ray source (Table 2, Paper I).

FBS $0950+664$ (RXS J09540+6608) has been identified on an objective prism plate as an AGN (Bade et al. 1998) ; our spectrum shows it to be a Seyfert 1 at $z=0.172$. Our new spectra of FBS $1235+699$ and FBS $1324+448$ confirm their redshift ( $z=0.521$ and 0.331 respectively). FBS $1715+406$ is Zw 225.094 or MCG 07.35 .061 , a 15.4 mag galaxy at $z=0.030$ (Marzke et al. 1996); according to Abramian \& Mickaelian (1994), it is an emission line galaxy; our spectrum shows that it is an absorption line galaxy, with a weak [ $\left.\mathrm{N}_{\mathrm{II}}\right] \lambda 6583$ line in emission at $z=0.029$.

The spectra of the four extragalactic objects are displayed in Fig. ??.

Fig. 1.- Spectra of the four extragalactic objects in Table ??.

## 3. NEW PUBLISHED DATA

Since the publication of Paper $I^{1} 51$ new bright ( $B<17.0$ ) AGNs have been discovered, at $|b|>30^{\circ}$, in the subarea of the FBS survey studied in this paper, bringing the total number of known such objects to 108 .

### 3.1. MAGNITUDE ESTIMATE

We have extracted, when available, the $O$ magnitudes of these 108 objects from the APS database (Pennington et al. 1993); these magnitudes are missing for five objects only (all at $\delta>63^{\circ}$ ). We have also extracted the $O$ magnitudes from the USNO-A2.0 catalogue (Monet et al. 1996) which, as the APS, is based on measurements of the $O$ plates of the Palomar Observatory Sky Survey I (POSS-I).

[^0]

Fig. 2.- Plot of the differences between the USNO $O$ and the photoelectric $B$ magnitudes $v s$ the photoelectric $U-B$ colors for 102 PG objects

Fig. 3.- Plot of the USNO vs the APS $O$ magnitudes for the bright AGNs listed in tables 2 and 3

To estimate the accuracy of these magnitudes, we have proceeded as for the APS $O$ magnitudes (see Paper I): we have compared the differences between the USNO $O$ and photoelectric $B$ magnitudes of 102 PG UV-excess stars vs their photoelectric $U-B$ colours (Fig. ??); we found a negligible colour equation, a rms dispersion of 0.31 mag , compared to 0.25 mag for the APS magnitudes, and a relatively large offset $\langle O-B\rangle=-0.38 \mathrm{mag}$ (to be compared with $\langle O-B\rangle=-0.16 \mathrm{mag}$ for the APS). Fig. ?? shows a comparison of the APS and USNO $O$ magnitudes for the bright AGNs; they are in reasonable agreement, except for five objects for which the USNO magnitudes are brighter by more than one mag than the APS magnitudes; these five objects are low luminosity Seyfert 1 galaxies at relatively small redshifts ( $z<0.13$ ) which probably explain the large magnitude differences; it seems that the USNO magnitudes for extended objects are grossly underestimated.

In Table ??, we list all bright ( $B<17.0$ ) AGNs found in the FBS subarea at $|b|>30^{\circ}$ with their APS and USNO $O$ magnitudes (when available) and the absolute $B$ magnitudes computed ${ }^{2}$ using the APS $O$ magnitudes increased by 0.16 mag (or the USNO $O$ magnitudes increased by 0.4 mag ), excluding the bright QSOs of our "complete" sample (listed in Table ??).

In the case of RXS J12110+7005 for which the APS magnitude is not available, Schwope et al. (2000) give $B=17.0$, while the USNO $O$ magnitude is 14.3 ; but this object has a moderate redshift ( $z=0.127$ ); moreover its APM $O$ magnitude (Irwin et al. 1994) is 17.66 ; we therefore adopted the Schwope et al. mag and excluded it from the "complete" sample.

### 3.2. THE NEW RADIO AND X-RAY BRIGHT QSOs

The FIRST Bright Quasar Survey (FBQS) was built by matching the VLA FIRST survey with the Cambridge Automated Plate Measuring Machine (APM) catalog of POSS-I objects (Irwin et al. 1994); it covers an area of $2682 \mathrm{deg}^{2}$ in the north Galactic cap; it contains 1238 objects brighter than 17.8 mag on the POSS-I $E$ plates (White et al. 2000). About 1180 square degrees are within the FBS area; they contain 38 FIRST radio sources identified with an AGN brighter than $B=17.0$ at $|b|>30^{\circ}$; nine are bright QSOs $\left(O_{\text {APS }}<16.0\right)$, three (CSO 900, FIRST J1306+3915 and RXS J17102+3344) being new. Although the numbers are small, this suggests that the "complete" sample we built in Paper I is only $67 \pm 15 \%$ complete.

According to White et al. (2000), QSOs with radio emission above the FIRST 1 mJy limit constitute about $25 \%$ of all QSOs brighter than $B \sim 17.6$, but for QSOs brighter than $B=16.4$, the FBQS QSO density is indistinguishable from the density of optically selected QSOs. Nevertheless, of the 15 bright QSOs known prior to the FIRST survey in the area common to the FIRST and FBS surveys, only six ( $40 \%$ ) have been detected as FIRST radio sources; therefore the complete

[^1]Table 2: Bright AGNs ( $B<17.0$ ) in the FBS subarea at $|b|>30^{\circ}$, excluding the bright QSOs listed in Table 3. Cols. 1 to 6 give the B1950 position, cols. 7 and 8, the APS and USNO-A2.0 $O$ magnitudes respectively, col. 9 the name, col. 10 the redshift, col. 11 the galactic latitude, col. 12 the absolute $B$ magnitude and col. 13 references for the newly identified AGNs: (1) Beuermann et al. identification of the FIRST sources with bright starlike objects could not yield a complete survey of bright QSOs.

A number of recent papers are devoted to the optical identification of RASS sources (Beuermann et al. 1999; Cao et al. 1999; Grazian et al. 2000; Schwope et al. 2000; Wei et al. 1999; Xu et al. 1999). One of the new identifications is RXS J12043+4330, a QSO at $z=0.663$ (Xu et al. 1999); it is also FBS $1201+437$ (FBS \#302) or PG1201+436, which had been classified as a DC white dwarf by Green et al. (1986). Its APS $O$ magnitude is 16.23 ; it is therefore not bright enough to be included in our "complete" sample.

Nineteen RASS sources are now identified with a bright QSO in the area discussed in this paper (including the three new FIRST QSOs); of the 17 FBS or BQS bright QSOs in our sample (Table ??), $12(70 \%$ ) are ROSAT All Sky Survey (RASS) X-ray sources, suggesting that the total number of bright QSOs is equal to $19 / 0.70=27$ (if all optically bright, X-ray sources have been discovered).

## 4. DISCUSSION

Our "complete" sample of bright QSOs (Table ??) contains 29 objects brighter than $B=16.16$ $\left(O_{\text {APS }}<16.00\right)$, three of them (indicated by a " N " in the last column of Table ??) are not within the PG area. The area common to the PG and FBS surveys at $|b|>30^{\circ}\left(\sim 2250 \mathrm{deg}^{2}\right)$ contains

Table 3: Bright QSOs $\left(B<16\right.$, and $\left.M_{B}<-24\right)$ in the FBS subarea at $|b|>30^{\circ}$. The columns are the same as in Table 2 with however two additional columns; an X in col. 14 indicates that the object is a ROSAT RASS source; a Y or an N in col. 15 indicates if the object lies or not in the PG area

26 bright QSOs (13 PG QSOs and 13 others) (but there are 17 PG QSOs with $B_{\text {PG }}<16.16$ in the area; this larger number is probably due to the Eddington (1940) effect, the PG magnitudes being affected by relatively large errors, $\sigma \sim 0.37 \mathrm{mag}$ ). From these data, we derive a surface density of $0.012 \mathrm{deg}^{-2}$, which is to be compared with the original value of the PG survey: $0.0064 \mathrm{deg}^{-2}$, implying a maximum completeness of $53 \pm 10 \%$ for the PG survey.

Grazian et al. (2000) have cross-correlated the RASS with photometric databases in an 8164 $\operatorname{deg}^{2}$ area of the northern sky at $|b|>30^{\circ}$, selecting all coincidences brighter than $R \sim 15.4$; from this, they derive a surface density of bright ( $B<15.5$ ) QSOs (defined as AGNs with $M_{B}<-23.0$ ) of $10 \pm 210^{-3} \mathrm{deg}^{-2}$ and conclude that the true surface density of such objects is about three times larger than that derived from the PG survey. However, they do not specify how the $B$ magnitude of their objects was derived. Their sample contains 46 QSOs; 15 of them have $z>0.20$; we have extracted from the APS catalogue the $O$ magnitudes for 12 of them (for the three others, these magnitudes are unavailable); it turns out that only one (J172320.5+341756) has $O<15.34$, corresponding to $B<15.5$, suggesting that the $O$ magnitudes used by Grazian et al. are underestimated and, consequently, the surface density overestimated.

Lamontagne et al. (2000) claim that they found a surface density of bright QSOs three times larger than the PG value. They have searched for UV-excess stellar-like objects with $B<16.5$ and $U-B<-0.6$ in a $840 \mathrm{deg}^{2}$ area covering the south Galactic cap; the errors in the $B$ magnitudes are estimated to be 0.30 mag rms . They have found 228 such objects which have all been spectroscopically identified; 32 are AGNs, out of which only eleven are brighter than $B=16.16$ and $M_{B}=-24.0$ (including 0117-2837 which, according to Grupe et al. (1999), has a redshift of 0.349 rather than 0.055 ). We derive a surface density or $0.013 \mathrm{deg}^{-2}$, in agreement with our value and only twice the PG value.

## 5. CONCLUSION

In Paper I, we compared the surface density of QSOs in the Bright Quasar Survey and in the First Byurakan Survey and concluded that the completeness of the BQS is of the order of $70 \%$; Wisotzki et al. (2000) have found that the BQS is $68 \%$ complete from a comparison with the Hamburg/ESO survey, in agreement with our previoys estimate. Based on a number of recently published data, as well as on our own new observations, we redetermined the surface density of QSOs brighter than $B=16.16$ in the BQS area to be $\sim 0.012 \mathrm{deg}^{-2}$, implying that the completeness of the BQS is $53 \pm 10 \%$. It should be stressed however that the numbers involved are quite small, and that larger areas should be investigated before a definitive value of the surface density of bright QSOs could be determined.
